THE COMMITTEE

Description of Invention:

Detection of a lens in a package is currently accomplished by back illuminating the package with diffuse light and observing with a camera-based vision system. This approach works well but to determine presence or absence. Specifically, the package is illuminated from top or bottom with a black body type source and the light transmitted through or reflected from the package and with a black body type source and the light transmitted through or reflected from the package and lens is filtered for the wavelength of interest and measured with a simple detector. The best region is the 2.5-3µm water absorption band which the water in the lens will absorb, as opposed to the non-hydroscopic package. In that cases the presence of a lens lowers the signal received to the detector over the 2.5-3µm band. It is also possible to detect preferential absorption in the UV region from both the UV photo initiator, and any UV blocker present, or the visible region from any tint present.
